Tube — Module Manual

Your own videos on your own installation, played by PeerTube clients

1 What the module does

A video is a document in your archive wearing the **Video** mask. Set its **Published** field to `yes` and PeerTube clients play it from your video host, streamed straight from storage; set it back to `no` and it is gone from the clients at once. The folder the video is in is its channel. Whoever may edit the video may publish it.

2 Setting it up

1. Under **Modules ▸ Tube**, enter the **Video host** (e.g. `video.example.com`) your proxy sends to the installation's `peertube` prefix, and the instance's name and description clients show.
2. File a video (an MP4 plays everywhere) in any folder, give it the **Video** mask, fill **Description** and, when you release it, **Published** = `yes` and **Published at** (the catalogue lists newest first). A **Thumbnail** is the id of an image document; **Duration seconds**, **Language** and **Tags** are shown by clients.

3 Limits

The module serves tenants that do not encrypt content at rest: a video's bytes go straight from storage to the player, and an encrypted object could only be served through the server. Such a tenant sees an empty catalogue, and the log says why. Files play as stored; there is no transcoding.
